A fossilised tail from a dinosaur that roamed the world 125million years ago has been discovered at the bottom of a crumbling cliff on the Isle of Wight.

Fossilised remains of the the dinosaur — believed to be an iguanodon — were embedded at the base a cliff-face near Brighstone.

Excavations and attempts to salvage the tail for detailed analysis are currently thwarted, due to safety risks posed by the crumbling cliff.

io is from Freshwater on the island and runs an online retail shop, Brighstone's Grange Farm and Isle of Wight Pearl.

She adds: 'But is in a seriously over-hanging cliff which seems to be crumbling constantly, so people need to be super careful.'

Experts are also urging locals to not attempt to extract the fossil for risk of damaging it or endangering themselves.

WHAT IS AN IGUANODON DINOSAUR?

Iguanodon is a genus of herbivorous dinosaurs which could grow to the size of an African elephant and run at 14mph (23kmh).

They walked the earth around 132 million years ago, during the Lower Cretaceous period.

They grew to around 10 feet (three metres) tall, 30 feet (10 metres) long and weighed 4.5 tons.

Different species flourished in both Europe and North America.

They would have been prey for one of England's biggest predators, Baryonyx, a relative of Spinosaurus.

These large dinosaurs were able to walk on both two legs or all four.

They had a highly specialised, five-fingered hand which would have made them excellent foragers.

The thumb spike is one of their best-known features.

It would have made an excellent stiletto-style weapon against predators and it also could have been used to break into fruit.

Scientists believed they held their long, heavy tail high in the air for balance.

The genus was named in 1825 by English geologist Gideon Mantell.
